eBoostr lets you use flash drive memory to boost up your Windows XP performance

Boost Windows XP with Flash Memory

MDO Ltd. announces the release of eBoostr, a complete replacement for Microsoft ReadyBoost technology for Windows XP.

Upgrade the performance of your PC without upgrading its components. Get ReadyBoost-like technology in Windows XP. Overcome ReadyBoost limitations and use up to four inexpensive flash devices to speed up your system. Add more speed to your PC without upgrading!

Upgrading computer components can be costly, and is not always possible. Buying and plugging a USB flash memory stick, on the other hand, is neither expensive nor complicated. That is why Microsoft developed a new technology called ReadyBoost. ReadyBoost uses flash memory plugged into a computer to enhance operating system responsiveness, decrease loading time, and improve computer performance.

Unfortunately, Microsoft ReadyBoost is only available in Windows Vista. Since the day Microsoft announced its ReadyBoost technology for Windows Vista, the company made it clear that no ReadyBoost upgrade will be released to support Windows XP and older operating systems.

eBoostr is a third-party implementation of speed-enhancing technology based on using flash memory to enhance the responsiveness and performance of a Windows XP computer. eBoostr works similar to Microsoft ReadyBoost, providing many of the same benefits to the end user.

Improved Performance with No Costly Hardware Upgrades

eBoostr improves the performance of any PC without having to upgrade its components or the operating system. Using flash memory allows Windows XP to access hard drives less frequently, which results in improved performance and responsiveness of Windows XP and all applications.

No ReadyBoost Limitations

ReadyBoost is a great technology, but it has its limitations. Its current incarnation does not support more than one flash memory stick or card at a time. ReadyBoost requires using fast flash memory that can be more expensive than the typical flash drive found on everyone's desk. Finally, ReadyBoost helps the most to those with little amount of RAM installed, and provides slim benefits to PCs with a gigabyte or more of RAM.

eBoostr overcomes these limitations. While it works great with ReadyBoost Certified devices, eBoostr also supports slower, less expensive flash memory sticks and cards, allowing for a really inexpensive way to improve your computer performance. eBoostr is not limited to a single stick or card, and supports up to four flash units simultaneously. Finally, unlike ReadyBoost, eBoostr provides noticeable performance benefits even to PCs that are stuffed with RAM sticks to the max.
